Coupled ion electrospray: quantitative analysis of low-molecular-mass compounds with low charge state by coupling with mass spectrometry. Ion-molecule interaction has been explored in a coupled ion/mass spectrometry (MS) system with low charge state, low mass, and high hydrophobicity. A highly sensitive source (EM-DB) has been designed with a new ion-catalyst interface. EM-DB samples were directly introduced into the source of a triple quadrupole MS. Total ion count, low mass range, and charge state of the analytes were greatly enhanced when the electrosprayed ions collided with active species injected from an electrospray nozzle. The ion current was further increased by replacing a portion of the introduced solvent with helium gas. More than 100 ions have been detected from 2.5 microM nicotinate mononucleotide (NMN), and about 300 ions have been detected from 1 mM l-leucine. The number of detected ions was increased depending on the active species and the ratio of introduced helium to solvent, and was in proportion to the injected sample amount. This study demonstrates that coupling ion/mass spectrometry with electrospray ionization may serve as a new method for quantification and monitoring electrospray-molecule interactions. Effects of elevated ambient temperatures on dystrophic chickens: Myostatin suppression and improved growth. This study quantified the effects of elevation of ambient temperatures on the growth, feed conversion rate, and myostatin suppression of 7- to 8-wk-old dystrophic (Avian muscular dystrophy) chickens. Full-sib progeny of a genetically homozygous flock of half-sib dystrophic chickens were used. After 7 wk of constant environmental conditions, each progeny was placed in a 12-cage, multiple-pen room. The ambient temperature was raised from 21 to 27 degrees C for 6 h/d for 10 consecutive days. From d 7, birds were provided a commercial diet to satiation four times per day. From d 0 to 10, dystrophic progeny with or without growth promoters were slaughtered. Growth rate was not affected by elevated ambient temperatures. All progeny were slaughtered, and carcass yield and breast meat
