and other organs, are sometimes damaged due to an accident or an illness. In order to treat such a medical condition, in the past, a physician would perform an invasive surgery such as a bone fracture, or a surgery involving the insertion of a medical implant. Unfortunately, invasive surgeries suffer from a number of drawbacks. Invasive surgeries are often traumatic, and require long recovery times, and in the case of oral and maxillofacial (OMF) surgeries, they are often associated with considerable pain and other complications. In contrast to invasive surgeries, minimally invasive surgeries, such as arthroscopic and open surgical procedures, have been shown to provide many benefits over invasive surgeries. As an example, the use of minimally invasive procedures for spinal stabilization and repair offers advantages over invasive surgical procedures. In these procedures, rods may be used in combination with posterior elements, such as pedicle screws and facet screws to stabilize and/or fuse adjacent vertebrae of the spine. In order to provide an effective stabilization of adjacent vertebrae, it is often necessary for the rod to be substantially rigid. In contrast to a typical bone that has a tensile strength of approximately 30 MegaPascal (MPa), the rigidity

of the rods used in current spinal procedures can often reach 85-120 MPa, sometimes even higher than 140 MPa. While the use of a solid rod allows for the implantation of pedicle screws and facet screws into multiple adjacent vertebrae at the same time,
