Field of the Invention The present invention relates to a technique for controlling a coordinate measuring device. 2. Description of the Related Art As disclosed in Japanese Unexamined Patent Application Publication No. 2003-245154, known is a coordinate measuring device, which includes a touch panel and a display which is positioned to be opposed to the touch panel. The display displays a command input screen, a measurement screen, and an axis direction screen. A processing section calculates a predetermined command by monitoring a user's command input through the touch panel. To display the input screen and the axis direction screen, for example, the processing section sequentially updates display states of the display. Also, the processing section displays the measurement screen according to a measured state of a coordinate measuring instrument, such as a probe, on the basis of the calculated command. A configuration of the processing section, which sequentially updates the display states of the display, includes a command table. The processing section reads a command that is displayed on the display from the command table, and updates the display according to the read command. If the processing section cannot read the command from the command table, the processing section updates the display without reading any command. There are different types of touch panels. For example, there is a resistive touch panel, a light receiving touch panel, and a capacitive touch panel. Each of the different types of touch panel has a characteristic that can be touched, cannot be touched, or other characteristic different from each other. The command table is also provided for each of the different types of touch panel. The processing section reads the command from the command table according to the type of touch panel. Accordingly, when the processing section does not read the command from the command table, the processing section updates the display without reading the command. Thus, the user cannot input a command for specifying a function of the coordinate measuring instrument in the

In some examples, software applications are used to generate and/or modify data. In some examples, the applications can modify or create data by applying a series of operations and/or procedures to the data. Some software applications may generate and/or modify data with data-processing and/or data-manipulation operations. In some examples, the data-processing and/or data-manipulation operations can include one or more operations and/or procedures that can be applied to different types of data. For example, an application that processes financial information can be used to add, remove, modify, or otherwise edit the data as necessary to perform its functions. As another example, a software application that converts video content can be used to apply one or more operations and/or procedures to the data as necessary to perform its functions. Because the software application is designed to process data, the software application can be used to modify and/or create data without regard to what data type the data was previously. If the software application is designed to modify or create data, the software application is often designed to manipulate data that is created by a wide variety of processes and/or procedures. In some examples, the software application includes one or more algorithms for use in the data-processing operations. However, it is often the case that the data-processing operations are not well optimized by these algorithms. In some cases, these algorithms perform suboptimal data-processing operations on the data. For example, some algorithms fail to perform as intended. It would be desirable to find ways to improve the performance of software applications.#!/bin/sh # #
