Next Limit Maxwell Render Suite 3.1 full Â· MadCar 3.ds Max 2015-2016Â .In a static random access memory (SRAM) cell, a bit of data is written to one memory cell, and as a result, the state of the memory cell switches between a high-impedance state and a low-impedance state. The high-impedance state may be referred to as a "0" state, whereas the low-impedance state may be referred to as a "1" state. To read data from the memory cell, a current is applied to a bit line (e.g., a high-impedance state corresponds to a relatively small current, whereas a low-impedance state corresponds to a relatively large current). As a result, the voltage of the bit line changes such that the current may be measured. The resulting current may be determined to correspond to the data in the memory cell. Most conventional SRAM cells have more than one port (e.g., two ports). The current (and the resulting voltage of the bit line) may be compared to a current reference (e.g., a current representing "1") in order to determine whether the bit line voltage corresponds to a low-impedance state or a high-impedance state. The bit line voltage may be compared to the current reference using two current comparators in parallel. The inputs of the current comparators may be tied together and may be biased by a current source. The present invention relates to a method for handling an anomaly that occurs during a cache miss and more particularly, to a method for handling an anomaly in a cache hit area. In a cache miss area where a processor is likely to miss a cache hit, processes that may benefit from the cache hit are prevented from being executed until the cache miss is cleared and stored data is once again in the cache hit area. Conventionally, a conventional cache miss algorithm prevents a processor from executing processes that may benefit from the cache hit until the cache miss area is cleared. However, such a conventional cache miss algorithm sometimes causes an increase in the duration of a time until a process is executed
